Packing methods

Chapter 7

INTRODUCTION

The chapter contains a survey of the packing methods most frequently used by Philips Semiconductors. It includes information that may be important to customers when making their purchasing decisions, for example the main dimensions, shapes, and packing quantities.

Standardization

For semiconductors, packing serves two important functions. The first and most obvious function is protection during storage and transport to customers. This, of course, applies to all products, not just semiconductors.

The second is to act as a delivery medium for automatic placement machines during equipment manufacture.

To do this effectively, the reels, trays and tubes that components are packed in must meet recognized standards. In this respect, Philips Semiconductors actively cooperates with standardization authorities throughout the world.

In addition, its packing methods meet all major international standards, including those of IEC (International Electrotechnical Commission), JEDEC (Joint Electron Device Engineering Council, USA) and NEDA (National Electronic Distributor Association, USA).

Environmental care

Nowadays, an important issue is environmental impact. Component and equipment manufacturers are continuously working to improve the environment friendliness of their products and packing, and have devoted much effort to eliminating the use of toxic materials and to looking at ways in which materials can be recycled.

In these respects, Philips Semiconductors has taken several important steps on the packing front. These include:

- Reducing the amount of packing material by switching to 'one piece' boxes (instead of boxes with upper and lower parts)
- Changing to 'mono material' to aid recycling. For example, from aluminium-lined boxes to carbon-coated boxes.
- Changing from white boxes to natural brown boxes to eliminate the use of bleach (chlorine) in their manufacture.

The aim is minimum waste and minimum environmental impact. We have already gone a long way towards this in the development of our packing methods. And future developments will take us even further along this route.

For more information relating to environmental issues, refer to Chapter 8 - Environmental data on ICs.

GLOSSARY OF TERMS

| | |
|----------------|---|
| Through-hole | mounted onto a PCB by insertion of leads into holes |
| Surface mount | mounted on the surface of a PCB |
| Package | container with terminals for an IC chip (also known as an envelope or outline) |
| Carrier | plastic tube, tray or tape with cavities, which can contain semiconductor products |
| Packing method | combination of a carrier and a box to protect products during transport and storage |
| Pin | rigid plastic pin that closes a tube for DIPs by insertion through holes in its end |
| Plug | flexible plastic plug that closes a tube for PLCCs or SILs by insertion into its end |
| Turnlock | rigid plastic pin that closes a tube for SOs by insertion into its end and turning to lock in place |
| SPQ | Smallest Packing Quantity, in one carrier |
| PQ | Packing Quantity, in a box containing one or more SPQs |

For a full definition of IC package abbreviations and their suffixes, refer to *Chapter 2 - IC Package range and dimensions*.

Packing methods

Chapter 7

DRYPACK FOR MOISTURE SENSITIVE SMDs

If packed or stored incorrectly, moisture-sensitive plastic SMDs can easily be damaged after a prolonged exposure to the high temperatures associated with certain soldering methods. If any moisture is present in the plastic package during soldering, it may turn into steam and expand rapidly. Under certain circumstances, the force exerted by this expansion can cause internal delamination or, in the most severe cases, may result in internal or external package cracks (the popcorn effect). This effect is more prominent with infrared and vapour-phase reflow soldering methods when soldering temperatures can reach severe levels.

To avoid this problem, and ensure trouble-free soldering, we deliver moisture-sensitive ICs in a resealable moisture-resistant plastic packing called a DRYPACK.

Moisture sensitivity level

Not all plastic packages are equally sensitive to moisture. To differentiate between types, we assign each IC package a moisture sensitivity level (MSL). The MSL of an IC's package is influenced by:

- chip area and size of the die-pad
- package body size
- package material properties
- moisture content of the package
- temperature and duration of the soldering process.

Determining MSL

We determine moisture sensitivity levels by testing batches of each package according to a detailed specification, which includes moisturizing and infrared-reflow soldering. This soldering method is used as infrared radiation is readily absorbed by the black IC packages and therefore is the most critical soldering process when testing for the popcorn effect.

After moisturizing to predetermined levels, the packages pass through an oven where they are first preheated, then heated to a soldering temperature, and finally cooled. The convection solder reflow requirements are given in Table 1.

To reduce any moisture-related stresses within the packages, they are first preheated to around 125 °C to allow them to dry before they reach their maximum temperature. The longer this preheating time, therefore, the smaller the chance of packages being damaged during the high temperatures associated with soldering.

Although the profile has a low maximum temperature, the packages are exposed to 183 °C and above for a relatively long time. If this maximum temperature is higher than that given in Table 1, the effect of soldering will be more severe compared with the test on which the MSL of the specific IC package is based. If, however, the package is soldered well within its specified floor life limit (see Table 2), a higher soldering temperature can be used as the package's moisture content will be much less.

Table 1 Convection solder reflow requirements⁽¹⁾

| PROFILE PARAMETER | REQUIREMENTS |
|--|---|
| Ramp-up rate (183 °C to peak) | 3 K/s max. |
| Preheat temperature (125 °C ± 25 °C) | 120 s max. |
| Temperature maintained above 183 °C | 60 to 150 s |
| Time within 5 °C of actual peak temperature | 10 to 20 s |
| Peak temperature range ⁽²⁾ | 220 °C +5 /-0 °C or 235 °C +5 /-0 °C |
| Ramp down rate | 6 K/s max. |
| Time from 25 °C to peak temperature | 6 minutes. max. |

Notes

1. All temperatures refer to the top side of the package as measured on the centre of the plastic body surface.
2. Peak temperature requirements:
 - a) Packages with a thickness ≥ 2.5 mm and all BGA packages: peak temp. 220 °C +5 / -0 °C.
 - b) Packages with a thickness < 2.5 mm and all with a package volume ≥ 350mm³: peak temp. 220 °C +5 / -0 °C.
 - c) Packages with a thickness < 2.5 mm and all with a package volume < 350mm³: 235 °C +5 / -0 °C.
(Package volume is defined as body-height × width × length, but excludes external leads and non-integral heatsinks).

Packing methods

Chapter 7

Table 2 Floor life versus moisture sensitivity levels⁽¹⁾

| MSL | CONDITIONS | FLOOR LIFE |
|------------------|----------------|------------|
| 1 | 30 °C / 90% RH | unlimited |
| 2 | 30 °C / 60% RH | 1 year |
| 2a | 30 °C / 60% RH | 4 weeks |
| 3 | 30 °C / 60% RH | 168 hours |
| 4 | 30 °C / 60% RH | 72 hours |
| 5 | 30 °C / 60% RH | 48 hours |
| 5a | 30 °C / 60% RH | 24 hours |
| 6 ⁽²⁾ | 30 °C / 60% RH | 6 hours |

Notes

1. Packages that are not sensitive to moisture do not require DRYPACK.
2. MSL 6 packages must be baked before use, after which they have a 6-hour floor life.

No problems are associated with wave soldering as the components are only exposed to high temperatures for a short time.

All Philips test centres perform these MSL investigations to the same rigorous specification, and classify the moisture sensitivity of packages into levels ranging from 1 (not sensitive to moisture) to 6 (very sensitive to moisture).

In addition, and as part of our Reliability Monitoring Program, we conduct regular stress tests on our SMDs. As part of these tests, the packages are exposed to a simulated moisturizing and soldering run to reproduce a typical production process, then they are checked both visually and electronically for any signs of deterioration. As a result, we guarantee that if the packages are stored correctly, IC reliability will not be affected after soldering.

Philips DRYPACK

The Philips DRYPACK is a laminated plastic packing that prevents the moisture content of the IC plastic packages rising above 0.1% by weight for up to one year. The DRYPACK must be stored at normal room temperature (between 10 °C and 30 °C), and in an atmosphere of less than 60% relative humidity (RH).

The DRYPACK contains a desiccant and a humidity indicator, used to monitor the moisture content when the bag is opened.

Using ICs from a DRYPACK

Before using ICs from a DRYPACK, it's essential that the humidity indicator is checked. If it shows that the RH has remained below 20% (the colour of the 20% dot is blue), the ICs are ready for use.

As soon as the ICs are removed for the DRYPACK, however, they are immediately exposed to moisture in the atmosphere. To prevent them absorbing excessive moisture, they must be soldered onto the PCB within the specified floor life period given in Table 2. These times are related to the MSL of the package.

If the humidity indicator in a DRYPACK shows an RH of more than 20% (the colour of the 20% dot has changed from blue to pink), the DRYPACK has been damaged, opened, or stored incorrectly. To prevent the popcorn effect in such a situation, the ICs that were in the DRYPACK must first be dried before soldering.

For example, the minimum drying time to reduce the moisture content of an IC package from an initial level of 0.3% by weight to around 0.05% by weight, is given by:

$$\text{Drying time (hours)} = 5 \times \text{package thickness (mm)} \text{ at a drying temperature of } 125^\circ\text{C} \pm 5^\circ\text{C}.$$

Note: High temperatures may deteriorate solderability. It is strongly recommended to dry at a maximum $125^\circ\text{C} \pm 5^\circ\text{C}$, and not to dry longer than required.

Resealing a DRYPACK

If some ICs from an opened DRYPACK are not used, the desiccant and the humidity indicator should be reinserted into the DRYPACK and the DRYPACK resealed within half an hour after opening using commercially available heat-sealing equipment

The time a resealed DRYPACK can be stored depends on the time since it was originally packed, and how long it was open before being resealed.
